

## REMARKS

Entry of the amendments to the specification and claims before examination of the application in the U.S. National Phase is respectfully requested.

If there are any questions regarding this Preliminary Amendment or the application in general, a telephone call to the undersigned would be appreciated since this should expedite the prosecution of the application for all concerned.

If necessary to effect a timely response, this paper should be considered as a petition for an Extension of Time sufficient to effect a timely response, and please charge any deficiency in fees or credit any overpayments to Deposit Account No. 05-1323 (Docket # 095309.57265US).

Respectfully submitted,

December 23, 2005

Exhaust gas cleaning system for an internal combustion engine

BACKGROUND AND SUMMARY OF THE INVENTION

[0001] The invention concerns an exhaust gas catalyst system for an internal combustion engine, with at least one catalytically active component according to the preamble of patent claim 1.

[0002] Catalytic converters ordinarily have a relatively restricted optimal thermal functioning range for ensuring proper cleaning of exhaust gas which in. In the case of NOx storage catalytic converters, for example, the optical range is between 190°C and 500° C. Below this range, they are not yet sufficiently catalytically active to be fully functional and to store the undesired pollutants contained in the exhaust gas and/or convert them into harmless substances; while above this range, a very strong deactivation is associated with a strong thermal aging occurs and finally a, which results ultimately in the destruction of the catalytic converter as a result of due to overheating. Since the temperature of the catalytic converter essentially is determined essentially by the temperature of the exhaust gases flowing through it, control, (in particular limiting, of the exhaust gas temperature through mechanical means and/or targeted cooling of exhaust gas is therefore of special importance for the proper operation of exhaust gas catalytic converters. No less important, however, is also the thermic behavior of the exhaust gas catalytic converters themselves, e.g.; that is: good temperature resistance in ranges of relatively high exhaust gas temperatures or good

light-off performance in order to be able to quickly reach their full catalytic activity so that efficient cleaning of exhaust gas is ensured.

[0003] A method for the treatment of exhaust gases of a diesel engine for the reduction of particle emissions is ~~known from~~ disclosed in German patent document DE 197 18 727 C2, in which the diesel exhaust gas is directed through two diesel catalytic converters arranged one behind the other, with the cell density of the downstream, second catalytic converter being greater than that of the first catalytic converter.

[0004] ~~The~~One object of the present invention is to provide an exhaust gas cleaning system for an internal combustion engine, ~~preferably~~especially for a diesel engine, in which reaction heat conversion is distributed uniformly over the entire length of the catalytically active components and aging behavior is improved.

[0005] ~~The invention achieves this object by providing an~~This and other objects and advantages are achieved by the exhaust gas cleaning system ~~with the features of claim 1. In this exhaust gas cleaning system, according to the invention, in which~~ the exhaust-gas-side surface of the catalytically active coating in the intake region of the catalytically active components has at least ~~partially~~ a partial diffusion layer, or is at least partially covered by a diffusion layer.

[0006] In a refinement of the exhaust gas cleaning system according to ~~claim 2, the invention,~~ the at least one region with high light-off temperature ~~in combination with~~ and a high temperature resistance (in contrast to the at least one other region with a low light-off temperature ~~in combination with a~~ reduced temperature resistance in comparison to the former ~~at least one~~

~~region~~ has a lower specific noble metal content and/or a larger noble metal particle diameter.

[0007] In ~~an~~another advantageous embodiment ~~according to claim 3,~~ the cell density in the intake region (higher and/or intermediate temperature region) of the catalytically active component is lower than in the discharge region (lower temperature region) of the catalytically active component.

[0008] ~~According to claim 4,~~ another feature of the invention, the catalytically active component is configured in its intake region with a support material ~~with~~that has a higher specific heat capacity, and in its discharge region with a support material with a lower specific heat capacity. As a result, a deactivation of the catalytic converter induced by a hot spot can be suppressed in a most advantageous manner ~~and,~~ while at the same time good light-off behavior can be achieved. For example, ceramic or ceramic-containing materials and/or metals or metal-containing materials as well as other materials suited to the particular application purpose can advantageously be used as supporting materials with differing specific heat capacity.

[0009] In an alternative refinement of the invention ~~according to claim 5,~~ the catalytically active component has a cone shape.

[0010] Furthermore, in ~~a refinement~~another embodiment of the invention ~~according to claim 6,~~ the catalytically active coating is in multiple layers, with the individual layers having differing composition. The at least one region with high light-off temperature in combination with a high temperature resistance is oriented toward the exhaust gas side, and the at least one additional region with a low light-off temperature in combination with reduced temperature resistance in comparison with the at least one

region<sub>1</sub> is applied to the side oriented away from the exhaust gas. The start-up temperature of a catalytically active component is referred to as light-off temperature.

[0011] In a preferred embodiment of the invention ~~according to claim 7,~~ the catalytically active coating with at least one region of high light-off temperature and with at least one further region with a low light-off temperature is applied in the form of a gradient, with the high light-off temperature being applied predominantly in the intake region of the catalytically active component and predominantly the at least one other region<sub>1</sub> with a lower light-off temperature being applied in the discharge region of the catalytically active component.

[0012] In a further preferred embodiment ~~according to claim 8,~~ the catalytically active coating ~~has~~includes predominantly or ~~wholly/entirely~~ the at least one further region with a low light-off temperature in combination with reduced temperature resistance.

[0013] The catalytically active component can, for example, be configured as an oxidation catalytic converter, an NO<sub>x</sub> storage catalytic converter, an SCR catalytic converter and/or as a particle filter.

[0014] ~~Advantageous embodiments of the exhaust gas cleaning system according to~~Further advantages of the invention are the object of the subclaims and will become evident from the description and from the drawing. ~~Furthermore, advantageous Exemplary~~ embodiments of the invention are presented in the drawings and are described below, wherein by way of example: illustrated in a simplified form in the drawing and will be explained in more detail in the following description. In the drawing:

## BRIEF DESCRIPTION OF THE DRAWINGS

[0015] FIG 1 ~~shows~~is a schematic depiction of a first embodiment of the invention

[0016] FIG 2 ~~shows~~is a schematic depiction of a second embodiment of the invention

[0017] FIG 3 ~~shows~~is a schematic depiction of a third embodiment of the invention

[0018] FIG 4 shows ~~at~~the conversion behavior of an NO<sub>x</sub> storage catalytic converter according to the state of the art

[0019] FIG 5 shows an optimized conversion behavior of an NO<sub>x</sub> storage catalytic converter according to the invention.

## DETAILED DESCRIPTION OF THE DRAWINGS

[0020] The schematic depiction of FIG 1 shows an arrangement of a catalytically active coating 1 using the example of an NO<sub>x</sub> storage catalytic converter. Exhaust gas catalytic converters ordinarily comprise a support material or a support body 6 with catalytically active coating 1 applied thereto, ~~which. The latter,~~ for example, can be applied to the support body by means of a porous washcoat of Al<sub>2</sub>O<sub>3</sub>, SiO<sub>2</sub>, TiO<sub>2</sub>, ZrO<sub>2</sub>, zeolites and/or mixtures thereof together with activity enhancing additives or promoters. Frequently serving as support body for catalytic converters are ceramic catalytic converters with a honeycomb-like structures, preferably of cordierite or other suitable materials. Alternatively, however, support bodies of metal can also be used. Furthermore, the catalytically active component can be

configured in its intake region with a support material with higher specific heat capacity and with a support material with lower specific heat capacity in its discharge region so that materials such as, for example, metal or metal-containing materials and ceramic or ceramic-containing material can be jointly utilized as support material or support body for a catalytic component. ~~As depicted in FIG 1, the catalytically~~

[0021] ~~As depicted in FIG 1, the catalytically~~ active coating 1 of the NO<sub>x</sub> storage catalytic converter is constructed of individual layers of differing composition. The at least one region with a high light-off temperature in combination with and a high temperature resistance 2 is directed toward the exhaust side, and the at least one other region with a low light-off temperature ~~in combination with~~ and a reduced temperature resistance 3 ~~in comparison (compared~~ with the at least one region being applied to the side directed away from the exhaust gas). Region 2 thus is characterized in comparison with region 3 by a poorer low-temperature activity, but a higher high-temperature resistance, while region 3 in contrast has an ~~opposed~~opposite behavior and is responsible for good overall conversion and good cold-start behavior. Through the incorporation of region 2 in the intake region of the catalytically active component, the activity in the lower and/or intermediate temperature range is reduced.

[0022] Regions 2 and 3 contain platinum-group metals, in particular platinum and/or rhodium, as catalytic converter material, as well as alkali or earth alkali metals, which are characterized by their storage capacity for oxides of nitrogen. This property is utilized in NO<sub>x</sub> storage or adsorber catalytic converters. Under lean operating conditions ( $\lambda > 1$ ), the nitric oxides are converted as follows:

[0023] Under rich exhaust gas conditions ( $\lambda < 1$ ), nitrogen dioxide is desorbed back out of the storage and is converted directly with the carbon monoxide present in the exhaust gas into nitric oxide:

[0024] The switch-over times between lean and rich operation of the engine depend on the quantity of storage material used, the  $\text{NO}_x$  emissions and the parameters typical for all catalyzed reactions such as gas throughput and temperature.

[0025] Furthermore, regions 2 and/or 3 can include oxygen storage components such as a cerium compound, with the most important substance being the cerium oxide. Oxygen storage components equalize the air ratio fluctuations in  $\lambda$ -1 regulated engines since they can change their oxidation state from +III to +IV and vice versa:

~~By~~In this ~~means~~manner, a constant air ratio is obtained. In addition, cerium supports the noble metal dispersion.

[0026] In order to control the temperature resistance of catalytic converter coatings, compounds of the elements La, Zr, etc., preferably as oxides, can also be contained.

[0027] The choice of the composition of regions 2, 3, in particular the concentration of noble metal in combination with the noble metal diameter, is closely bound with the particular exhaust gas temperature window to which respective regions 2, 3 are exposed. As a result, the catalytic activity of the regions can be controlled ~~alongside~~along with other measures. Through a lower concentration of noble metal and/or a larger particle size it is possible first to avoid excessively large conversion immediately after intake into the catalytic converter. As a result, ~~by which means an~~ excessively high temperature and loads on the intake side of the catalytic converter can be avoided. Second, it can be provided through the selection of a relatively large concentration of noble metal and of a relatively small particle size that in the downstream region the required activity for conversion of the pollutants is present in sufficient degree, or can even be increased.

[0028] Furthermore, the exhaust-gas-side surface of catalytically active coating 1 in the intake region of the NO<sub>x</sub> storage catalytic converter at least partially has a diffusion layer 4 or is at least partially covered by a diffusion layer 4. The diffusion layer itself essentially contains oxides of aluminum, cerium and/or zirconium and causes a kinetic retardation of the chemical reactions proceeding at this location, in particular transport or diffusion processes. ~~By~~In ~~this means~~manner, temperature peaks, (so-called hot spots,) are advantageously suppressed in the catalytic converter intake region, and the thermal load in the intake region is reduced, ~~without in so doing~~ impairing the cold start behavior of the system.

[0029] The manufacture of catalytic converters is well documented in the literature in terms of the general procedure.

[0030] By variation of the cell densities (in the intake region of the catalytic converter lower cell densities, for example 200 to 400 cpsi, and in the discharge region of the catalytic converter higher cell densities, for example 600 to 900 cpsi) and the use of conical catalytic converter structures (a narrower catalytic converter diameter in the intake region and an increasing diameter in the discharge region), the sojourn time for the exhaust gas in the different catalytic converter regions can be controlled, ~~i.e.~~ That is, in the intake area high flow speeds prevail while in the back region, a longer sojourn time of the exhaust gas and thus a greater conversion plays a role.

[0031] FIG 2 is a schematic representation of an example of a variant according to the invention of a catalytically active coating 1 using the example of a NO<sub>x</sub> storage catalytic converter. (For the sake of simplicity, the same reference characters are used for the same components or components achieving the same function and to this extent reference can be made to the above description for FIG 1.) In other respects, the advantages mentioned in FIG 1 and in the general part of the description likewise apply for the embodiment according to the invention in FIG 2 and for all subsequently mentioned embodiment forms.

[0032] ~~FIG 2 shows by way of example in schematic representation a variant according to the invention of a catalytically active coating 1 using the example of a NO<sub>x</sub> storage catalytic converter, with for the sake of simplicity the same reference characters being used for the same components or components achieving the same function and to this extent reference can be made to the above description for FIG 1. In other respects, the advantages mentioned in FIG 1 and in the general part of the description likewise apply~~

~~for the embodiment according to the invention in FIG 2 and for all subsequently mentioned embodiment forms.~~ The exhaust gas aftertreatment apparatus of FIG 2 includes a catalytically active coating 1 with at least one region with high light-off temperature ~~in connection with~~ and a high temperature resistance 2~~2~~, and with at least one other region with a low light-off temperature ~~in combination with~~ and a reduced temperature resistance 3 in comparison with the at least one region. The region 5, comprising the regions 2 and/or 3, ~~are [sic]~~ is applied in the manner of a gradient to the catalytic converter support, ~~within:~~ Within the intake area E of the catalytic converter predominantly the region with high light-off temperature 2 ~~being~~ is applied, and in the discharge area A of the catalytic converter ~~predominately~~ predominantly the at least one other region with a low light-off temperature 3 ~~being~~ is applied. The exhaust-gas-side surface of the catalytically active coating 1 in the intake region of the NO<sub>x</sub> storage catalytic converter likewise has at least partially a diffusion layer 4~~4~~, or is at least partially covered by a diffusion layer 4.

[0033] FIG 3 ~~shows in~~ is a schematic representation ~~by way of an~~ of a further variant according to the invention, of a catalytically active coating 1 using the example of an NO<sub>x</sub> storage catalytic converter, in the case of which region 3 is provided on the catalytic converter support. The exhaust-gas-side surface of the catalytically active coating 1 in the intake region of the NO<sub>x</sub> storage catalytic converter in like manner ~~has here also~~ has at least one diffusion layer 4~~4~~, or is at least partially covered by a diffusion layer 4.

[0034] In FIG 4, the total conversion of ~~the a conventional~~ a conventional NO<sub>x</sub> storage catalytic converter is plotted as a function of the catalytic converter length. The steep rise of the curve at the beginning clearly shows the high activity of the catalytic converter and the associated high exothermy of the reaction in

its intake region. This leads to a premature aging or even damage in the intake region of the catalytic converter.

[0035] FIG 5 in contrast demonstrates an optimized conversion behavior, which is retained with all embodiment forms according to the invention, ~~with it being~~. It is possible to utilize the recommended measures for optimization of conversion individually or in combination. Through the invention, the conversion (and above all the associated exothermy, i.e. the quantities of heat released in the catalytic reaction) advantageously are distributed more uniformly on the entire NO<sub>x</sub> storage catalytic converter. The thermic load of the first region of the catalytic converter region is thereby reduced, without impairing the cold-start behavior of the system ~~being thereby impaired~~. In addition, temperature peaks in the intake region are thus effectively avoided.

[0036] The foregoing disclosure has been set forth merely to illustrate the invention and is not intended to be limiting. Since modifications of the disclosed embodiments incorporating the spirit and substance of the invention may occur to persons skilled in the art, the invention should be construed to include everything within the scope of the appended claims and equivalents thereof.

~~DaimlerChrysler AG~~

Abstract

The invention concerns an exhaust gas cleaning system for an internal combustion engine with at least one catalytically active component which is configured such that its catalytically active coating (1) comprises at least ~~one~~ a first region with high light-off temperature ~~in combination with~~ and a high temperature resistance (2) and at least ~~one further~~ a second region with a low light-off temperature ~~in combination with~~ and a reduced temperature resistance (3) ~~in comparison with~~ relative to the ~~at least one first~~ region). The exhaust-gas-side surface of the catalytically active coating (1) in the intake region of the catalytically active component has at least ~~partially~~ a partial diffusion layer (4), or is at least partially covered by a diffusion layer (4).
